Above diagram depicts how a query is processed in the database to show the result. When a query is submitted to the database, it is received by the query compiler. It then scans the query and divides it into individual tokens. Once the tokens are generated, they are verified for their correctness by the parser.

The SQL Server Database Engine processes queries on various data storage architectures such as local tables, partitioned tables, and tables distributed across multiple servers. The following topics cover how SQL Server processes queries and optimizes query reuse through execution plan caching.

Query Processing Architecture Guide - SQL Server ...

A complex database consists of many tables storing a large amount of data. A query allows you to filter the data into a single table so that you can analyze it more easily. Queries also can perform calculations on your data or automate data management tasks. You can also review updates to your data before committing them to the database.

What Is the Definition of a Database Query?

Stage 1: The query is sent from the data consumer to the data virtualization server. Stage 2: For each virtual table, the optimizer of the data virtualization server determines in which data store it's stored. For each data store, a query is generated. This is an optimization process.

Multi-database. In this method dynamical schema will be created based on the database to be connected to. For example, if the user connects to DB2 database, then a schema will be created dynamically to connect to DB2 database and make the user query flexible with this schema, if he connects to Sybase DB, then schema will be created dynamically to connect and perform Sybase transactions.

Involves the structure (primary key and its attributes) of the entity. If the primary key is unique and all attributes are scalar and fully dependent on the primary key, then the integrity of the entity is good. In the physical schema, the table's primary key enforces entity integrity.

The activities include translation of queries in high-level database language, into expressions that can be used at the physical level of the file system, a variety of query-optimization transformations, and actual evaluation of queries.

Describe query processing in distributed database

Data definition – Creation, modification and removal of definitions that define the organization of the data. Update – Insertion, modification, and deletion of the actual data. Retrieval – Providing information in a form directly usable or for further processing by other applications. The retrieved data may be made available in a form basically the same as it is stored in the database or in a new
